Host shifts

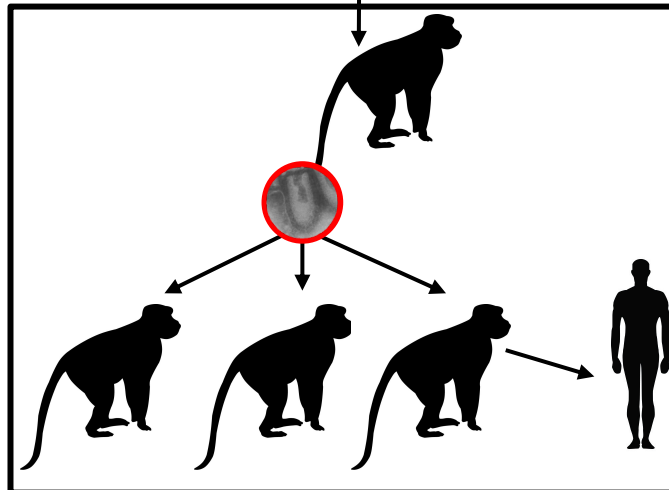

Exposure

Infection
and
evolution

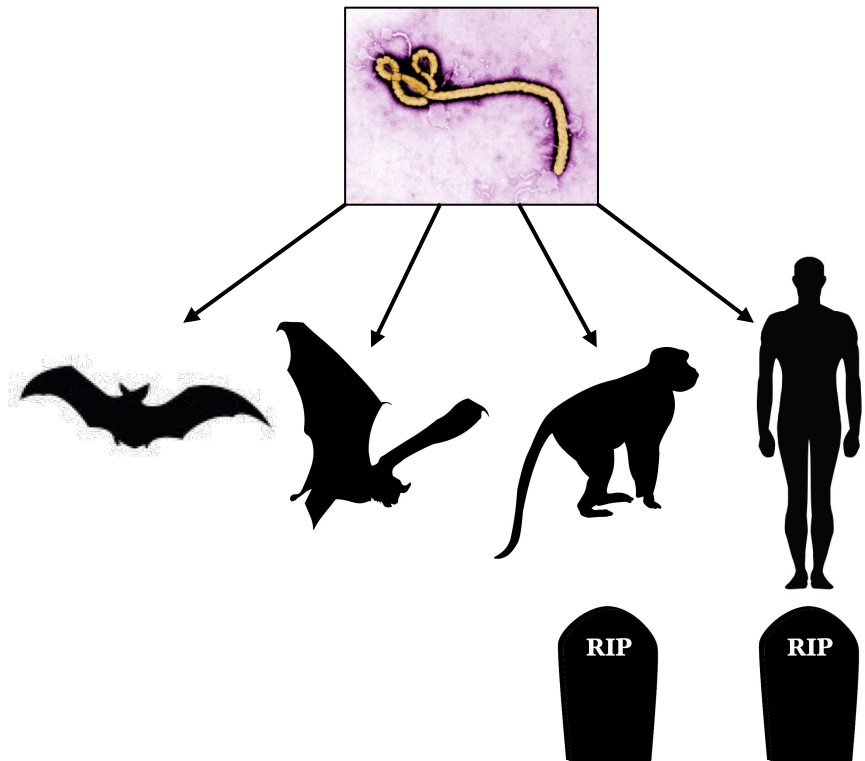

Transmission

Changes in virulence following host shifts

- Virulence = the harm a parasite does to its host
- Virulence following a host shift can be high, e.g:

- Ebola
- Influenza
- SARS coronavirus
- Hendra virus

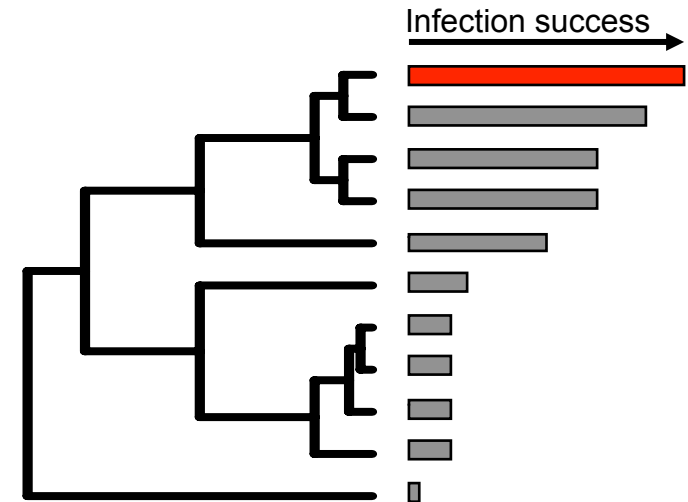

The host phylogeny and virulence

- Host phylogeny is important determinant of host shifts

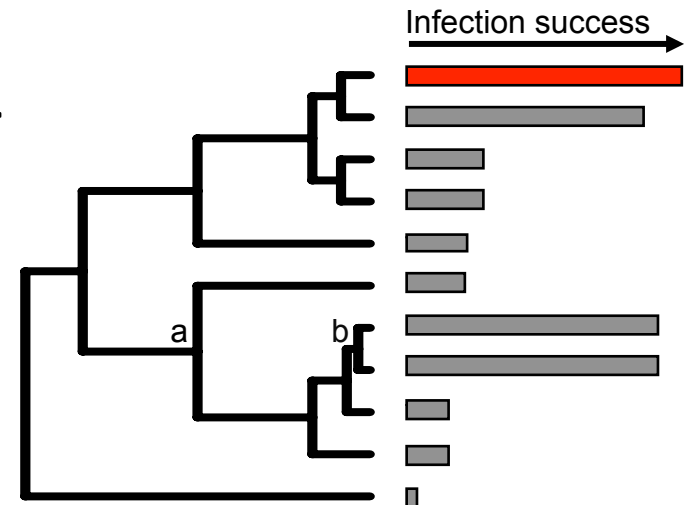

- genetic distance from the natural host

= 'distance effect'

- groups of related hosts show similar levels of susceptibility independent of distance from natural host

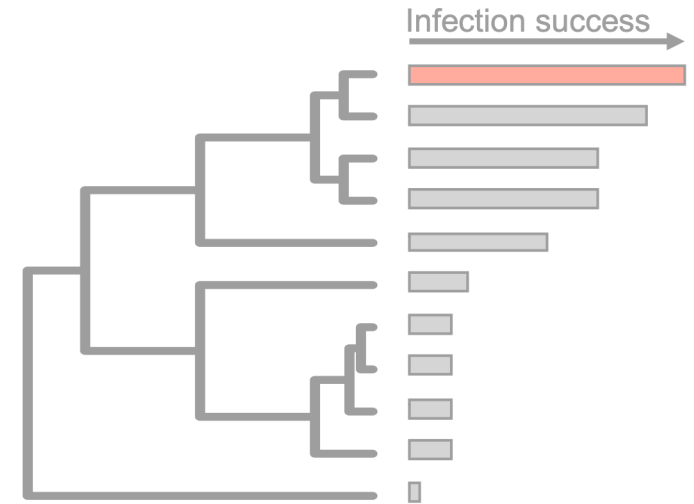

= 'phylogenetic effect'

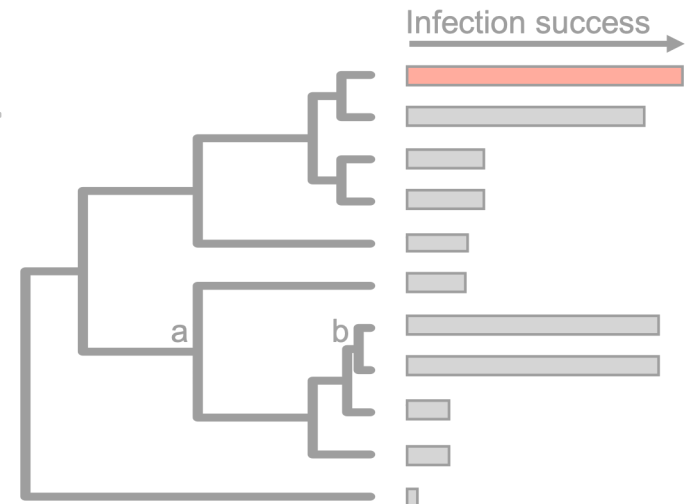

The host phylogeny and virulence

- Host phylogeny is important determinant of host shifts

▪ genetic distance from the natural host
= 'distance effect'

▪ groups of related hosts show similar levels of susceptibility independent of distance from natural host
= 'phylogenetic effect'

- Is pathogen virulence determined by the host phylogeny?

Study system

- Hosts: 48 species of Drosophilidae
- Pathogen: Drosophila C virus (DCV)
 - positive sense RNA virus in the family *Dicistroviridae*
 - naturally infects *D. melanogaster*
 - horizontally transmitted

Dicistrovirus

Images: Huszar and Imler 2008

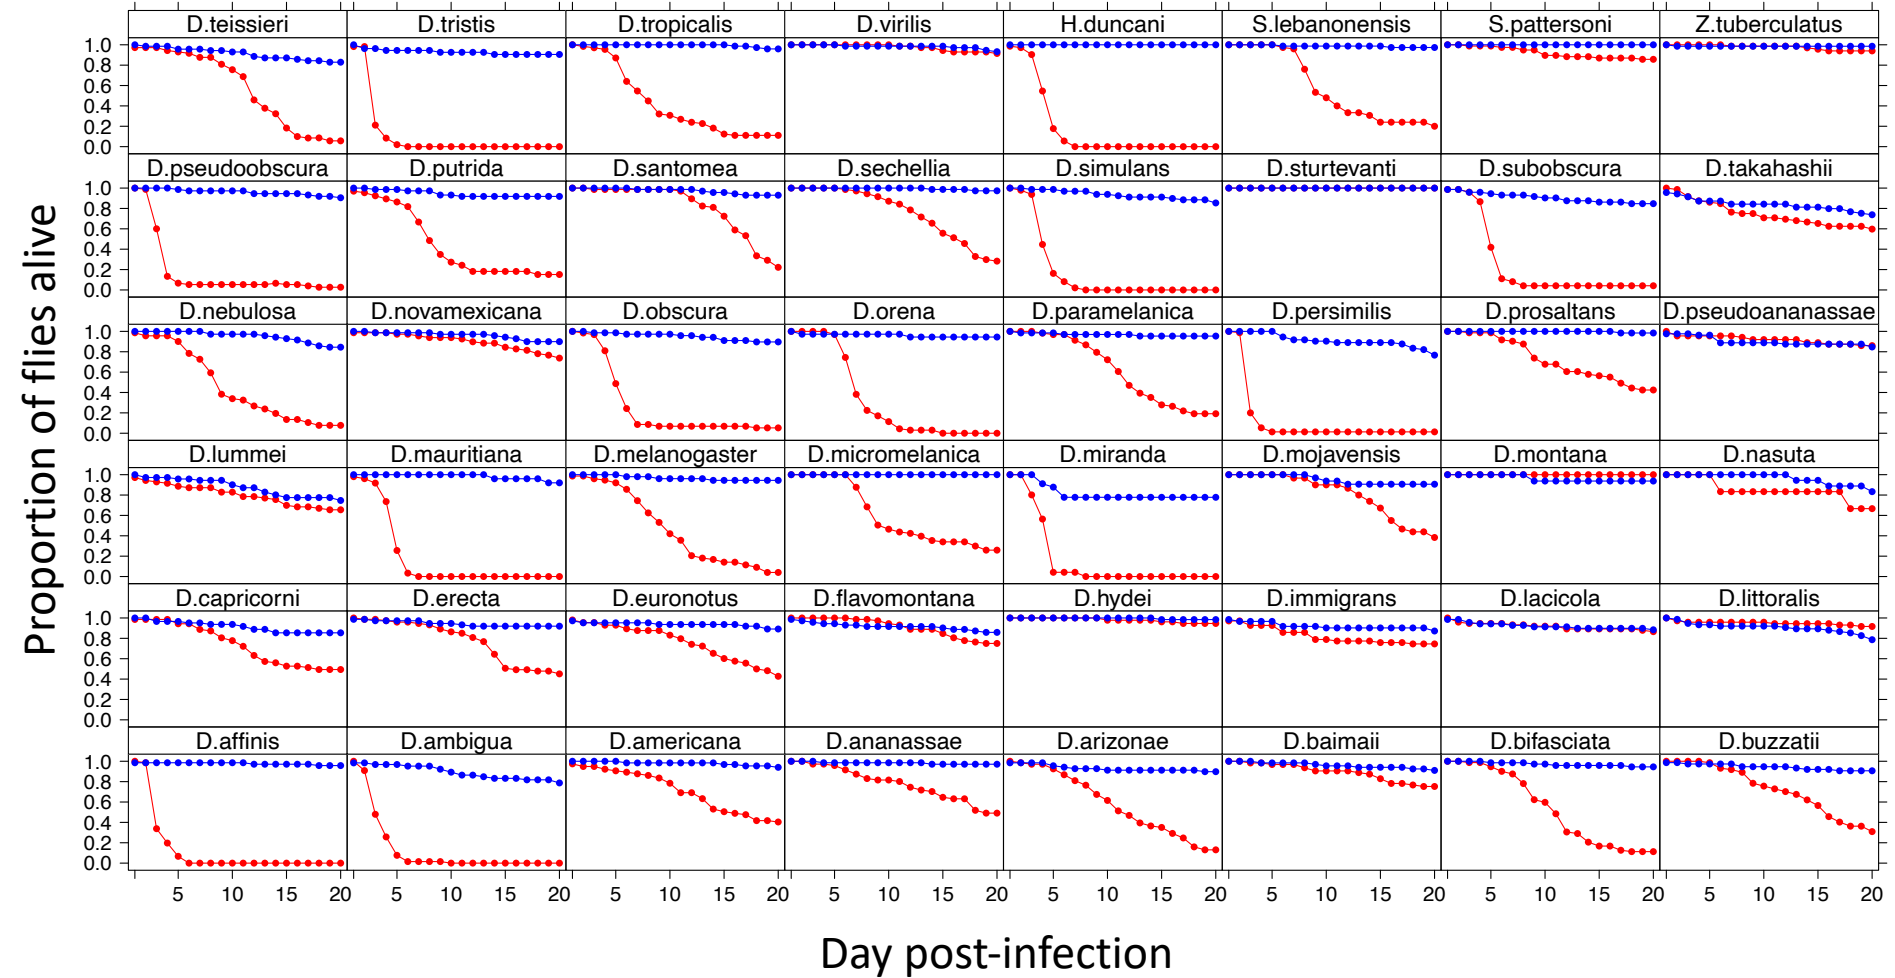

Experimental design

- Infected 48 species of fly with DCV
- Virulence= mortality for 20 days post-infection
- Also measured the change in RNA viral load with qRT-PCR

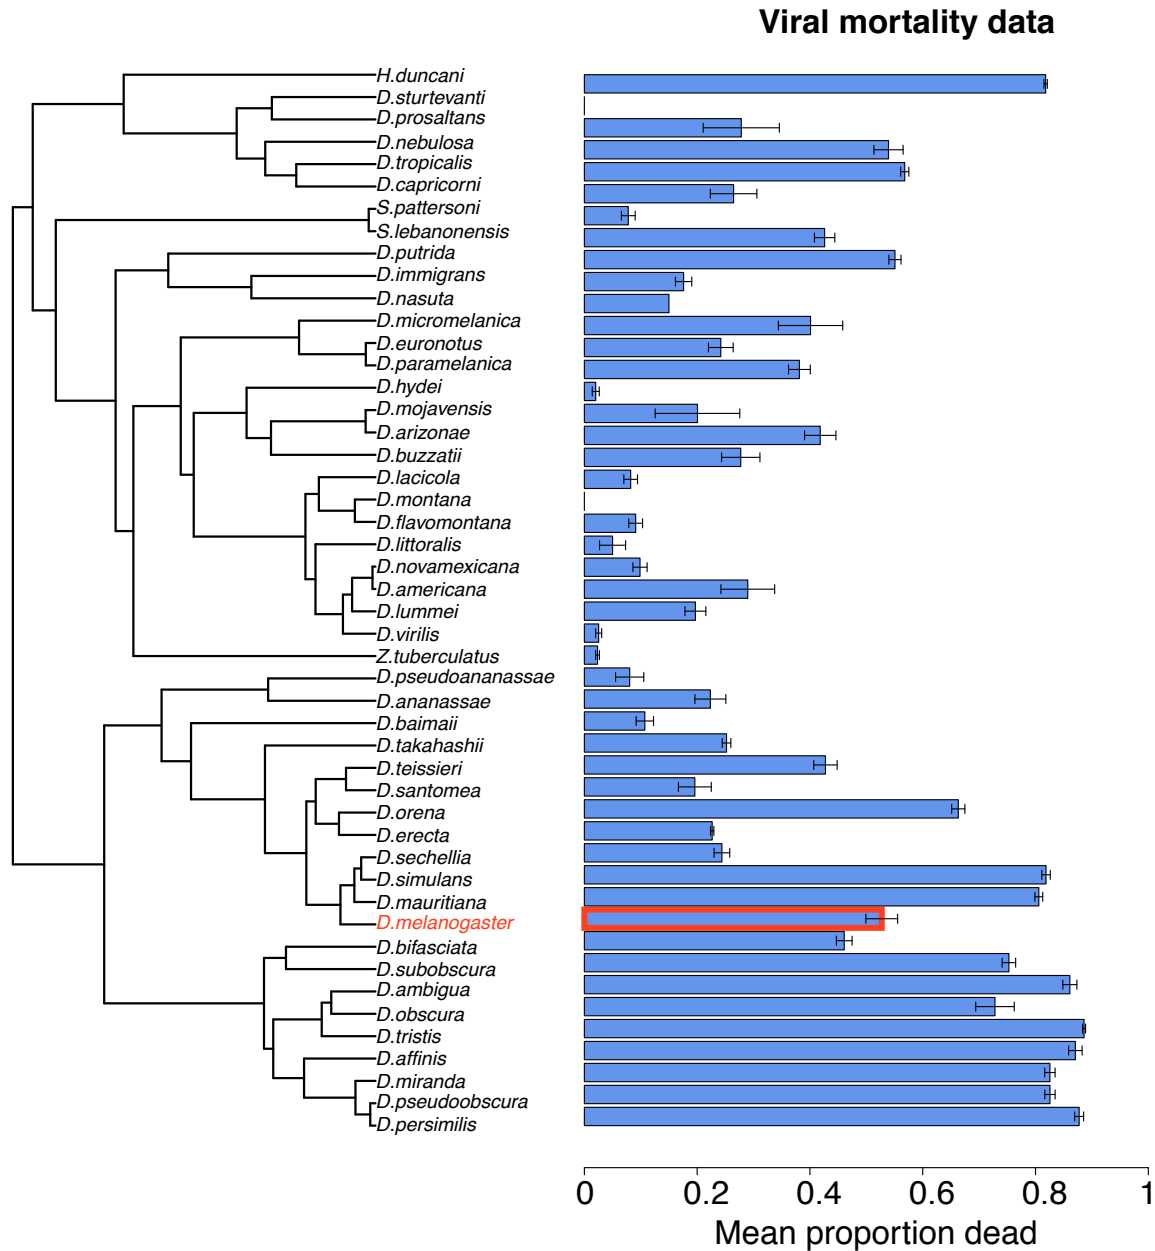

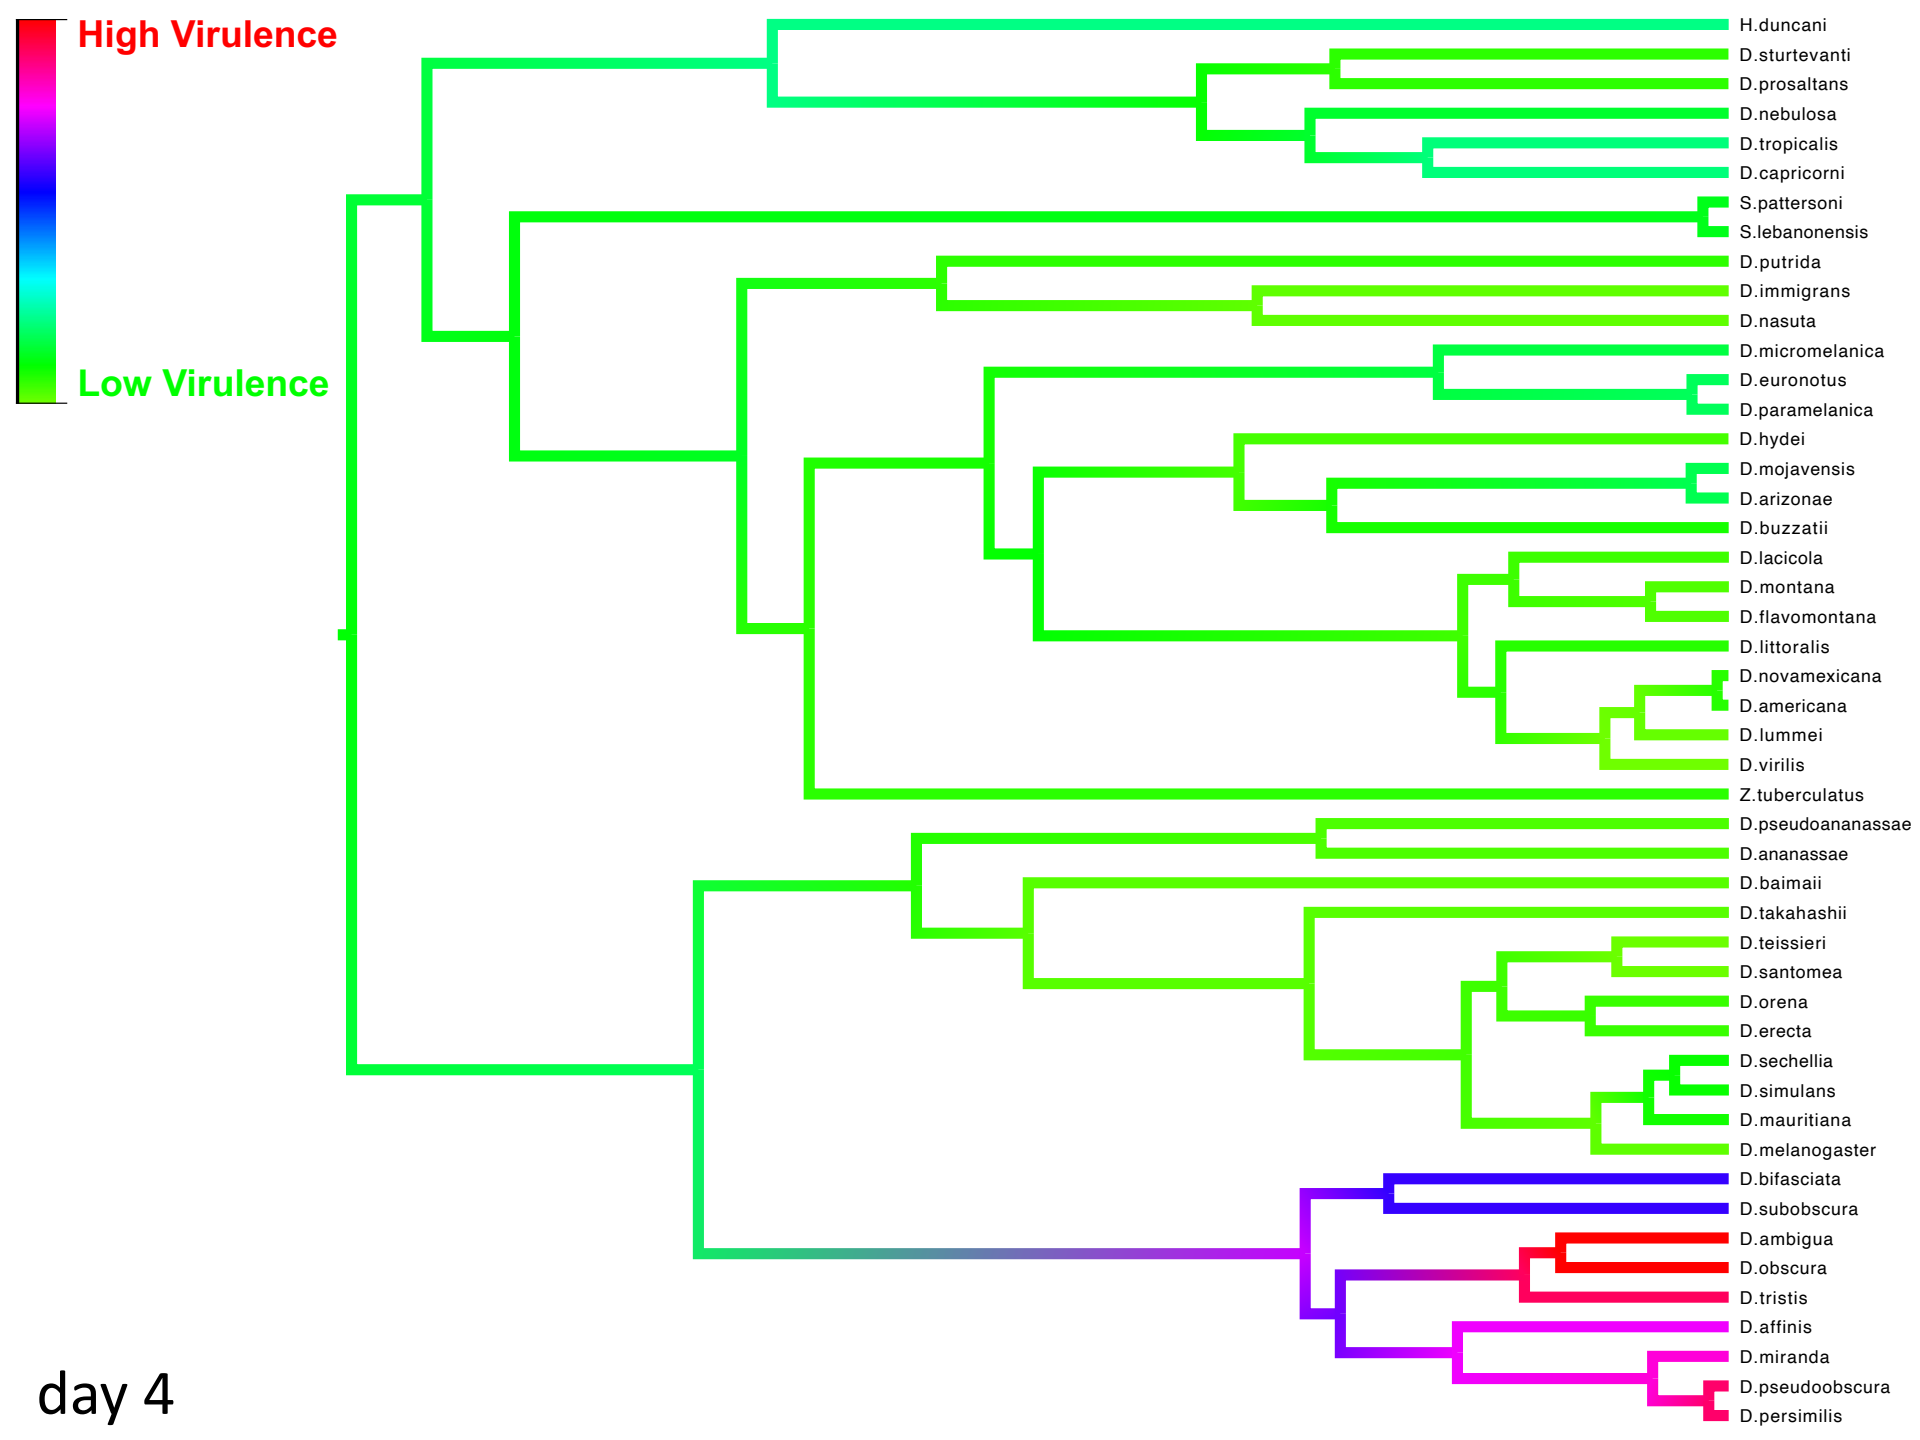

Virulence

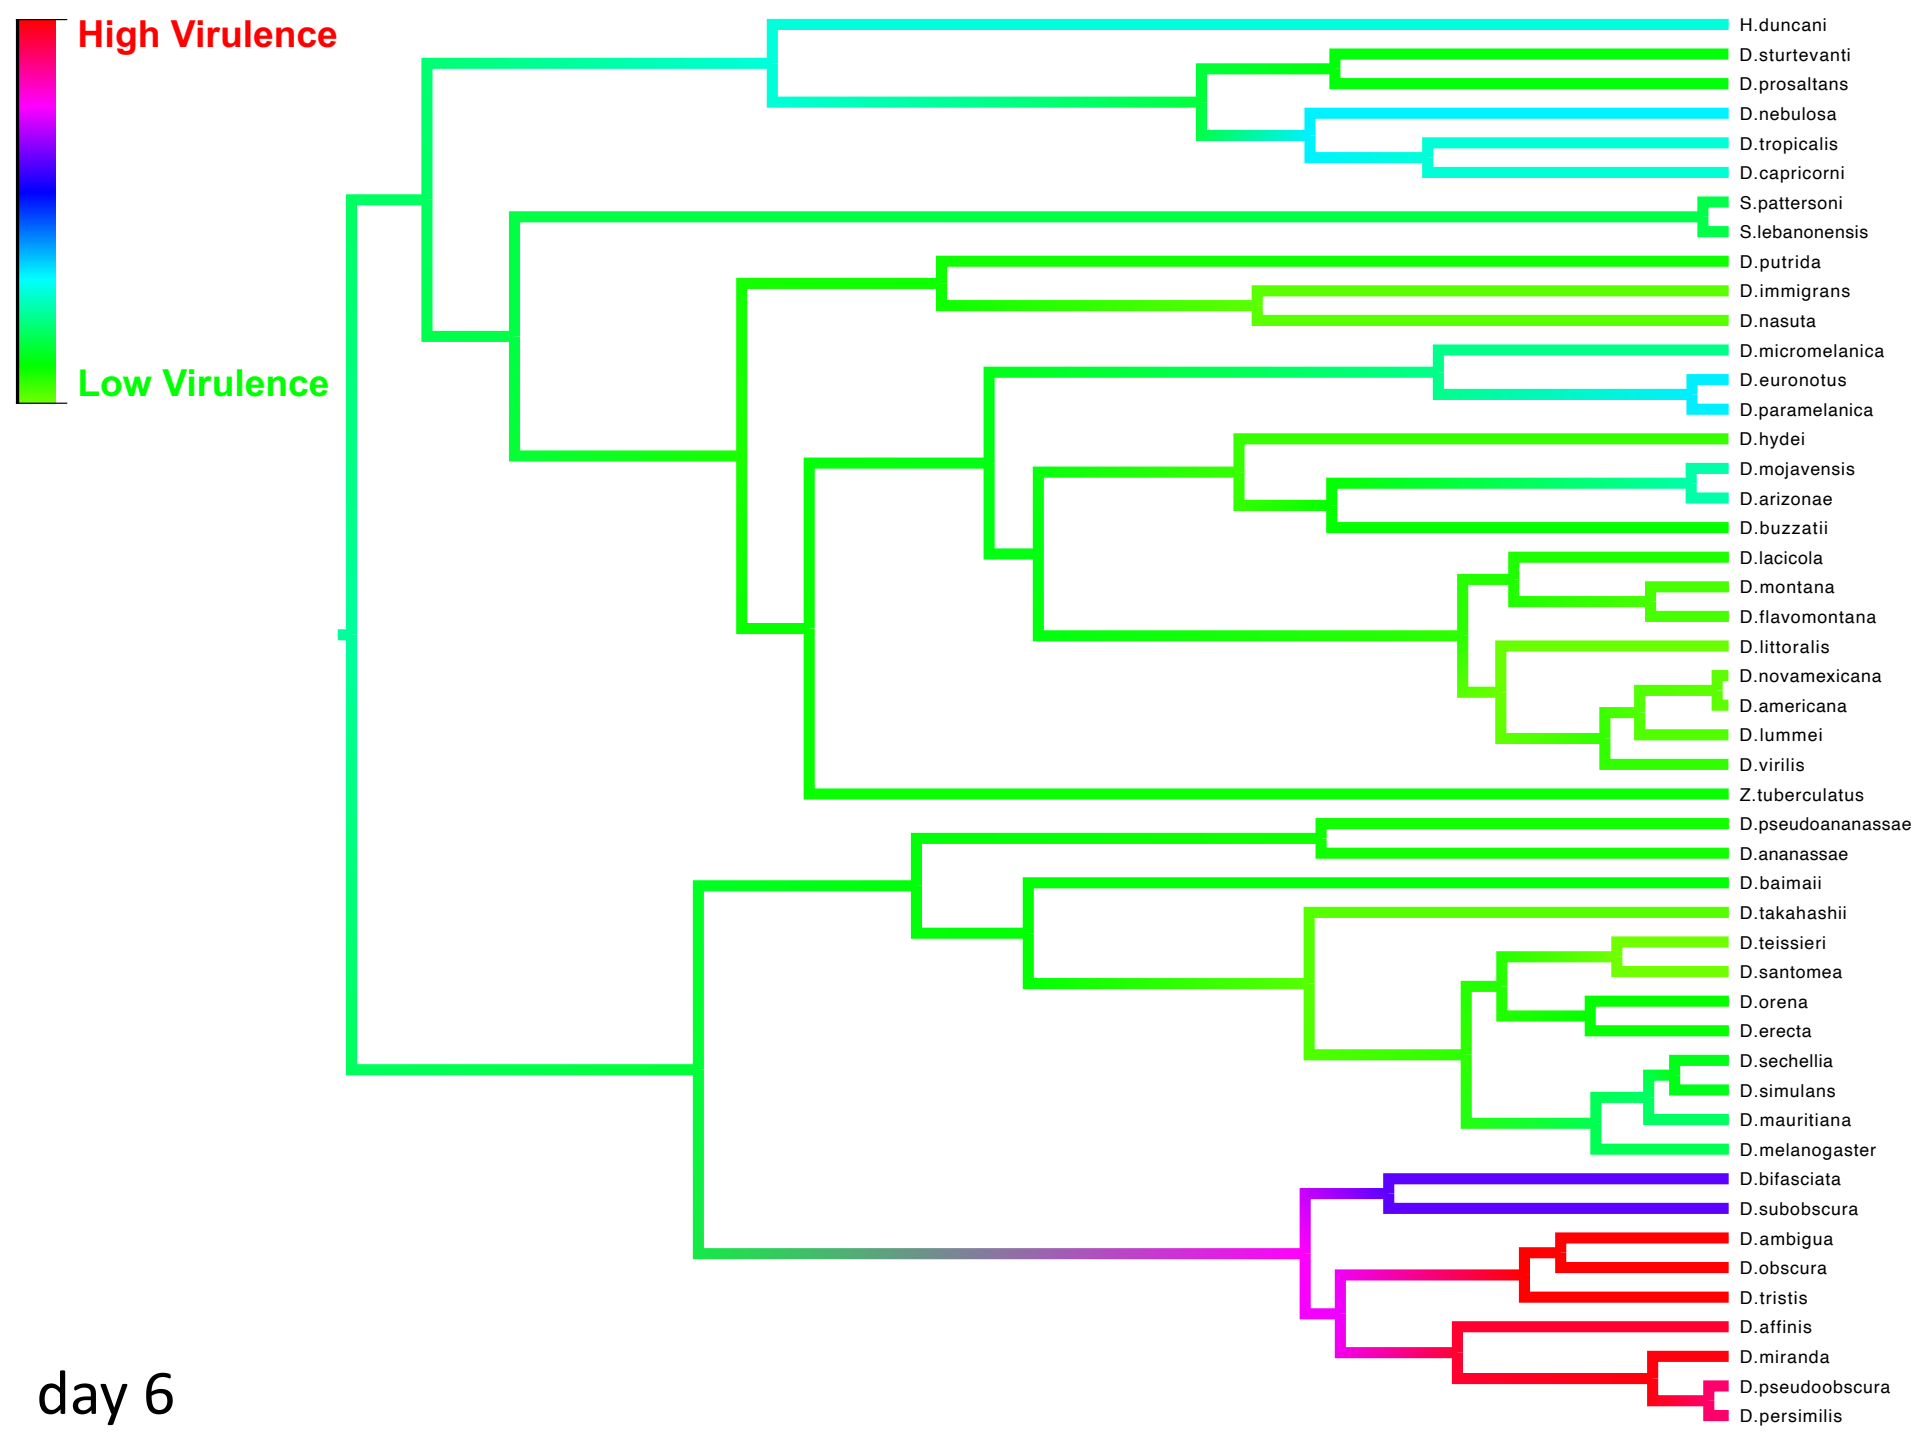

Virus and Control treatments

Analysis

- Phylogenetic mixed model (MCMCglmm)
- Fixed effect= distance from the natural host
- Random effects= V_p (phylogeny), V_s (species), V_e (residual)
- Phylogenetic effect= $V_p / (V_p + V_s)$

Model: Distance effect

- No effect of distance from the “natural” host on virulence

Model: Phylogenetic effect

- No effect of distance from the “natural” host on virulence
- The host phylogeny explains a large amount of the variation in:
 - Virulence: **75%** (95% CI= 48%-97%)

Model: Phylogenetic effect

- No effect of distance from the “natural” host
- The host phylogeny explains a large amount of the variation in:
 - Virulence: **75%** (95% CI= 48%-97%)
 - Viral load: **67%** (95% CI= 33%-93%)

Phylogenetic effect

- No effect of distance from the “natural” host
- The host phylogeny explains a large amount of the variation in:
 - Virulence: **75%** (95% CI= 48%-97%)
 - Viral load: **67%** (95% CI= 33%-93%)
- Closely related species have similar levels of virulence and viral loads

Phylogenetic effect: ancestral traits

Virulence

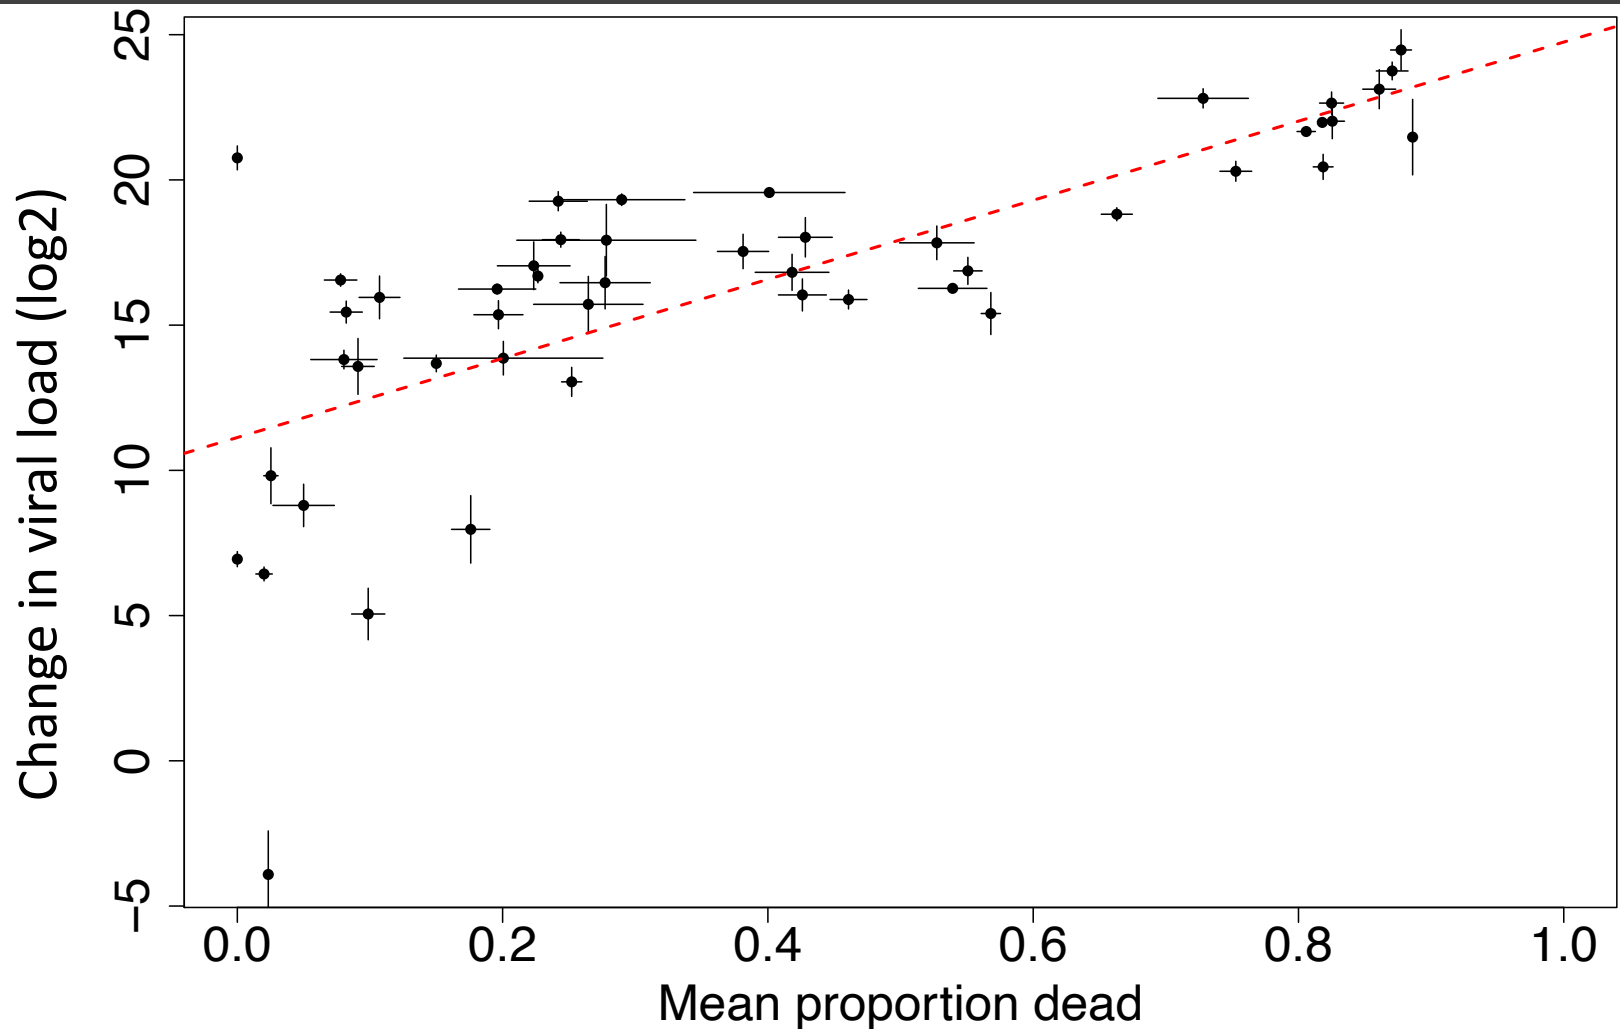

Viral load

Low virulence  High virulence

Low viral load  High viral load

Correlation between viral load and virulence

Phylogenetic correlation = 0.76 (0.44-0.99)

Environmental factors

Tissue tropism and transmission ecology predict virulence of human RNA viruses

Liam Brierley ^{1*}, Amy B. Pedersen , Mark E. J. Woolhouse 

Centre for Immunity, Infection and Evolution, Institute of Evolutionary Biology, University of Edinburgh, Edinburgh, United Kingdom

Abstract

Novel infectious diseases continue to emerge within human populations. Predictive studies have begun to identify pathogen traits associated with emergence. However, emerging pathogens vary widely in virulence, a key determinant of their ultimate risk to public health. Here, we use structured literature searches to review the virulence of each of the 214 known human-infective RNA virus species. We then use a machine learning framework to determine whether viral virulence can be predicted by ecological traits, including human-to-human transmissibility, transmission routes, tissue tropisms, and host range. Using severity of clinical disease as a measurement of virulence, we identified potential risk factors using predictive classification tree and random forest ensemble models. The random forest approach predicted literature-assigned disease severity of test data with mean accuracy of 89.4% compared to a null accuracy of 74.2%. In addition to viral taxonomy, the ability to cause systemic infection was the strongest predictor of severe disease. Further notable predictors of severe disease included having neural and/or renal tropism, direct contact or respiratory transmission, and limited ($0 < R_0 \leq 1$) human-to-human transmissibility. We present a novel, to our knowledge, comparative perspective on the virulence of all currently known human RNA virus species. The risk factors identified may provide novel perspectives in understanding the evolution of virulence and elucidating molecular virulence mechanisms. These risk factors could also improve planning and preparedness in public health strategies as part of a predictive framework for novel human infections.

SARS-CoV-2, SARS-CoV, and MERS-CoV viral load dynamics, duration of viral shedding, and infectiousness: a systematic review and meta-analysis

Muge Cevik, Matthew Tate, Ollie Lloyd, Alberto Enrico Maraolo, Jenna Schafers, Antonia Ho

Summary

Background Viral load kinetics and duration of viral shedding are important determinants for disease transmission. We aimed to characterise viral load dynamics, duration of viral RNA shedding, and viable virus shedding of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in various body fluids, and to compare SARS-CoV-2, SARS-CoV, and Middle East respiratory syndrome coronavirus (MERS-CoV) viral dynamics.
